`csvCombine` creates a data frame from a user-specified directory's (csv) files. The user can specify how many files to combine (default is all in `directory`).

To do:

1. extend to other file types
2. error-checking to exclude files of the wrong type

```
csvCombine <- function(directory, id = NULL) {  
  ## create a list of files in "directory"  
  files_list <- list.files(directory, full.names=TRUE)  
  
  ## create an empty data frame  
  data <- data.frame()  
  
  ## if "id" is null (default behavior), reset id to the length of the  
  ## "files_list" vector (i.e., the number of files in "directory")  
  if (is.null(id)) { id <- length(files_list) }  
  
  ## loop through the files, rbinding them together  
  for (i in id) {  
    data <- rbind(data, read.csv(files_list[i]))  
  }  
}
```
